constant, while metallic vanadium, in accordance with its p-type conductivity, has a positive Hall constant. The effective carrier concentration  $n^*$  and its Hall mobility were determined with the aid of the Hall constants obtained. Results are compiled in Table 1. As may be seen from Fig. 1, the K-absorption edge undergoes a considerable and regular alteration in the case of increasing silicon content. Only that point of the edge remains unchanged, which characterizes the position of the original absorption range in the energy spectrum. The absorption maximum shifts toward higher energies on a transition of metallic vanadium to the silicides with rising Si content, and on a further transition to V<sub>2</sub>O<sub>5</sub>. Owing to the invariable position of the original absorption range, the shift of the maximum leads to a widening of the edge and, hence, causes the "mean point" of the K-edge to shift toward shorter wavelengths. With increasing Si content the width of the K-edge approaches that of V<sub>2</sub>O<sub>5</sub>, which is a compound with a large part of ionic bond. This indicates a polarization of the metal atoms in the silicon-rich silicides and a heteropolar component in metal-silicon compounds.

This is in good agreement with results obtained from a quantum-mechanical calculation of the energy spectrum of electrons for molybdenum disilicide (Ref. 9). The authors finally discuss the behavior of the ultra-longwave absorption maximum A (Fig. 1), which is connected with the transition of K-electrons in the region of hybridized 3d-states of transition metal atoms. The authors believe that the shift of absorption maximum A is related to the d-states perturbed by the surrounding silicon atoms. There are 1 figure, 1 table, and 10 references: 6 Soviet, 2 German, 1 US, and 1 British.

TITLE: X-Ray Spectrum Analysis of Titanium Beryllides

PERIODICAL: Doklady Akademii nauk SSSR, 1960, Vol. 135, No. 3,  
pp. 642 - 644

TEXT: The authors refer to the obscure points found in literature concerning atomic interaction in beryllides of transition metals. They wanted to clarify this problem by studying the fine structure of X-ray spectra of titanium beryllides. The specimens were, besides pure titanium metal, TiBe and TiBe<sub>2</sub> prepared by the Institut metalloceramiki i spetsplavov AN USSR (Institute of Powder Metallurgy and Special Alloys of the AS UkrSSR) and placed at the authors' disposal by G. V. Samsonov. The apparatus used for the X-ray spectrum analysis had been described in Refs. 8,9. Both the fine structure of the absorption spectrum (exposure 4-6 h at 15 kv, 40 ma) and the fluorescence spectrum (fine structure of the K $\beta_5$  line) (exposure 20-40 h, 15 kv, 70  $\mu$ a) were photographed. A shift

Card 1/4

B004/B060

of the  $K\beta_5$  line, as well as of points m and A of the edge of the absorption band was observed in beryllides, as against the Ti spectrum. Fig. 1 illustrates this shift, taking the position of the  $K\beta_5$  line in pure titanium as the zero point of graduation. The relative position of these points on the energy scale (ev) is shown in Table 2:

$K\beta_{5\max}$	m	A
Ti 0	6.7 0.2	17.8 0.5
TiBe 3.8 0.2	7.5 0.2	23.0 0.3
TiBe <sub>2</sub> 3.8 0.2	7.2 0.2	22.6 0.3

1 figure, 2 tables, and 9 references: 5 Soviet and 4 German.

The experimental data are indicative of a metallic character of titanium beryllides, the valence electrons being common to both atoms. The donor-acceptor interaction between 3d electrons of Ti and 2s electrons of beryllium is bound to be small. There are

TITLE: The fine structure of X-ray absorption K-spectra of  
the metal in the homogeneous region of titanium  
nitride

PERIODICAL: Fizika metallov i metallovedeniye, v. 12, no.3, 1961,  
360-364

TEXT: X-ray spectrographic studies of titanium carbide were  
published earlier. The present work investigated the effect of  
concentration changes of the titanium nitrogen system in the  
region where only the phase TiN exists (30-50 at.% N). Samples  
containing 11.7, 12.8, 14.7, 15.4, 17.5, 18.1, 18.8, 20.6, 21.2  
and 22.4 wt.% nitrogen were prepared by the method given by Samsonov  
and his team (Ref.5: Sb. Metallokeramicheskiye materialy i  
metody ikh issledovaniya, AN USSR, Kiyev, 1959, p.53 (Symposium:  
Cermets and methods of studying them, AS Ukr.SSR, Kiev, 1959, p.53)).  
X-ray phase analysis showed that in all the specimens only one  
phase existed with a NaCl-type lattice having a parameter

increasing from 4.212 to 4.235 kX with increasing nitrogen content. X-ray spectrographic studies were carried out on apparatus described earlier by I.B. Staryy, (Ref.7: Izv. AN SSSR, ser. fiz., 1958, Vol.20, 798). The crystalline structure of titanium nitride is always octahedral. Decreasing nitrogen content in the nitride phase, although maintaining the octahedral coordination, should lead to a reduction in the role of the p-functions, decreasing their contribution to the d-band and therefore decreasing the coefficient of absorption in the corresponding spectral region; this was actually observed for all compositions, except those with 21.2 and 22.4 wt.% nitrogen, which very nearly correspond to the stoichiometric composition of TiN. Another explanation of the change in the fine structure of absorption spectra is that in the nitride phase there is a considerable ionic component in the bonds which decreases with transition from the samples deficient in nitrogen to the compound with stoichiometric composition. This is confirmed by results of measurements of the electrical properties and microhardness of the samples. S.N. L'vov and V.F. Nemchenko are mentioned in the article for their contributions in this field.

TITLE: Fine structure of X-ray absorption K-spectra of titanium  
in complex solid solutions of the TiC-TiN system

PERIODICAL: Akademiya nauk SSSR. Doklady, v. 140, no. 5, 1961, 560 - 562

TEXT: This is a contribution to the extensive experimental and theoretical material on carbides and nitrides of transition metals. S. V. Samsonov et al. (DAN, 135, no. 3, (1960)) studied the electrical properties of the TiC-TiN system. The authors used Samsonov's specimens for their tests. The K-absorption edge of titanium was examined with an X-ray spectrograph (G. V. Samsonov et al., Dop. AN USSR, 8, 838 (1958)). The analyzer was a bent

quartz crystal, in which the (1011) plane was the reflecting plane (radii of curvature, 2600 and 1650 mm). The X-ray photon energy was determined with an error of  $\pm 0.3$  ev. K-absorption edges of 7 alloys of the system under consideration, averaged from three measurements, are shown in Fig. 1. The dotted theoretical curves fit the experimental, continuous curves. The theoretical curves of the absorption edges were obtained on the assumption

that the metal atoms in the octahedral neighborhood change gradually during the transition from pure nitride to pure carbide, and that one metalloid is statistically replaced by the other. This process is accompanied only by a slight change of the lattice constant (about 3%) and a monotonic diminution of the carrier concentration. The authors think that the 3d conduction band of the metal in carbides and nitrides is little filled. The donor-acceptor interaction of the 3d electrons of titanium with the conduction electrons of metalloids is insignificant. The structural changes of the K-absorption edge during the transition from pure carbide to pure nitride are monotonic (Fig.1). The structure of the absorption edge becomes more distinct with increasing carbon content in the vicinity of the titanium atoms. This fact is connected with the scattering power of metalloid atoms. The results obtained are in good agreement with those of G. V. Samsonov (Sborn. nauchn. tr. Mosk. inst. tsvetn. met. i zolota im. M. I. Kalinina, no. 30, v. 1 (1957); ZhTF, 26, 299 (1950)). G. V. Samsonov, Corresponding Member AS UkrSSR, is thanked for providing the specimens and for participating in the work. There are 1 figure and 19 references: 14 Soviet and 5 non-Soviet. (Institut problem materialovedeniya Akademii nauk UkrSSR)TITLE: The  $K_{\beta}$ -spectrum of x-ray fluorescence in metallic scandium and some of its high-melting compounds

SOURCE: AN SSSR. Doklady, v. 170, no. 3, 1966, 548-551

TOPIC TAGS: scandium, scandium compound, fluorescence spectrum, x ray spectroscopy

ABSTRACT: The structure of the valence bands in metallic scandium and its carbide, boride, nitride and oxide (Sc, ScC, ScB<sub>2</sub>, ScN, Sc<sub>2</sub>O<sub>3</sub>) were investigated in a study of the fine structure of  $K_{\beta}$  emission lines in these materials. Due to low stability of metallic Sc and some of its compounds, the samples were placed in a vacuum and excitation was brought about by means of a sealed copper tube (30 kv, 30-35 ma). The (1010) plane of a bent quartz crystal was used for analyzing the spectrum. The resolving power of the spectrograph was 10,000. Except for a small shift (1 ev toward the long wavelength side) observed for the ScC the short wavelength side of the  $K_{\beta}$  line remained unchanged in shape and position. The shape and position of the  $K_{\beta_5}$  line appears to be

Card 1/3

UDC: 539.26

ACC NR: AP6032850

most sensitive to the changes in chemical bonding. In contrast to the shape exhibited by Sc, in its compounds the  $K_{\beta_5}$  line shows two distinct maxima. The compounds where the covalent and ionic contributions to bonding are stronger, the intensity of the short wavelength maximum is less.  $\text{ScB}_2$  shows the strongest tendency toward covalent bonding. The position of the two peaks for  $\text{ScB}_2$  supports the idea that the short wavelength maximum corresponds to the metallic Me-Me bond and the long wavelength maximum to the covalent Me-B bond. The spectrum of  $\text{ScC}$  shows two approximately equivalent maxima, both shifted by about 2 ev toward the shorter wavelength. This is in good agreement with previous notions that the strong bonding forces in high temperature transition metal compounds exist due to an almost equivalent contribution to bonding of the covalent and metallic d electrons. The spectrum of  $\text{ScN}$  shows the largest difference between the two maxima. The short wavelength maximum has the higher intensity and width. The increased contribution of the 2p states of N to the 3d band of Sc increases the probability of emission. The metallic nature of bonding in the nitride is supported by the disappearance of the long wavelength maximum of the K absorption edge (reported previously) and the closeness of approach between the  $K_{\beta_5}$  emission line (2p+3d states) and its satellite (2s states of the metalloid). It follows from this that the separation between the  $K_{\beta_5}$  and  $K_{\beta''}$  lines can, to a certain degree, be used to characterize the energy levels of the valence bonds of the metal and the metalloid. Whenever these lines come close, one can expect the metallic exchange interaction to pre-

Card 2/3

ACC NR: AP6032850

vail over the covalent interaction. Among the high temperature compounds involving transition metals of the first period (of those that have thus far been investigated), ScN, TiC, VC and CrB show the greatest degree of approach between  $K_{\beta_5}$  and  $K_{\beta''}$  (the sum of the valence electrons among the interacting atoms approaches a stable octet). This characteristic of the high melting compounds leads one to suspect that certain regularity exists in their energy spectra. The melting points of the Sc compounds decrease in the same order (ScN + ScC + ScB<sub>2</sub> + Sc<sub>2</sub>O<sub>3</sub>), in which the 2s and 2p + 3d bonds separate. Presented by Academician G. V. Kurdumov on 24 November 1965. Orig. art. has: 1 table, 1 figure.

TITLE: The fine structure of the x-ray absorption K-spectra of scandium in metal  
and in solid refractory compounds

SOURCE: AN SSSR. Doklady, v. 150, no. 6, 1963, 1260-1262

TOPIC TAGS: x-ray absorption, K-spectra, scandium, titanium, vanadium, hydrogen,  
boron, carbon, nitrogen, scandium nitride, scandium carbide, x-ray

ABSTRACT: In previous works by Zhurakovskiy et al., the fine structure of the K-spectra of titanium and vanadium, combined with hydrogen, boron, carbon, and nitrogen, was related to the nature of chemical interactions in these phases and to the properties of the compounds. The present work deals in a similar manner with scandium and its compounds. The work was motivated by theoretical, as well as by practical reasons, inasmuch as scandium nitride and carbide have a high melting point (approximately 3000°) and a high electrical conductivity. The absorption was measured in pure metal, ScB<sub>2</sub>, ScC, ScN, and Sc<sub>2</sub>O<sub>3</sub>. The absorption spectra are given in a figure, and their characteristic differences are pointed out. In particular, the long wavelength maximum does not remain same

Card 1/2

L 12625-63

ACCESSION NR: AP3003220

in the compounds as in pure metal, but is shifted toward the shorter wavelength indicating a different kind of interatomic interaction in the crystallographic phase than in the case of titanium and vanadium. The authors express their gratitude to I. Frantsevich, Academician, AN UkrSSR, for his constant attention and interest in the work." The paper was presented by Academician G. V. Kurdyukov on 21 Jan 1963. Orig. art. has: 1 figure.

TITLE:

The fine structure of X-ray K-absorption spectra of titanium in complex solid solutions of the TiC-TiN system

PERIODICAL:

Poroshkovaya metallurgiya, no.6 , 1962. 01-84

TEXT: The properties of refractory compounds of the transition metals are investigated using samples of TiC-TiN alloys obtained from G. V. Samsonov. These samples were cut from the centre of hot pressed billets of TiC-TiN mixtures containing 25, 33, 50, 67 and 75% of one component. For determining their phase composition the samples were analysed by X-ray diffraction. The K-absorption edge was obtained using a bent quartz crystal spectrometer (radii quartz crystals 2600 and 1650 mm) which enable X-ray photons to be determined to an accuracy of 0.3 eV. The change in fine structure observed as the composition of the alloy is altered agrees very well with the theoretical formula:

$$\mu(\lambda) = \mu_1(\lambda)x + \mu_2(\lambda)(100 - x).$$

Card 1/2

The fine structure of X-ray ... S/226/62/000/006/012/016  
E039/E535

where  $\mu_1$  and  $\mu_2$  are the absorption coefficients of Ti in TiC and TiN respectively and x is the percentage content of one phase in the complex solid solution. It is shown that the degree of filling of the 3d-state of the metal and the nature of its interaction with metalloid atoms remains practically unchanged as the composition of the alloy is altered. There is 1 figure.

TITLE: Roentgenospectral analysis of the force of chemical bond in hydrides of refractory metals on the example of titanium and vanadium compounds

SOURCE: Vysokotemperaturnyye metallokeramicheskiye materialy. Inst. metalloker. i spets. spl. AN Ukr.SSR. Kiev; Izd-vo AN Ukr.SSR, 1962, 19 - 28

TEXT: There are only indirect data available on the type of interatomic interaction in hydrides. The authors attempted for the first time to obtain direct information on the density of electron distribution over the energies in titanium and vanadium hydrides and to check by means of spectroscopy the hypothesis on the presence of a metallic bond between metal and hydrogen atoms in hydrides. For this purpose the authors investigated the fine structure of X-ray absorption K-spectra of titanium in hydrides with 1.2 and about 3 weight % H, and of vanadium in hydrides with 0.12; 0.28; 0.475; 0.75; 1.1 and 1.45 weight % H.

Roentgenospectral analysis of the...

Absorption edges of initial metals were also studied. To eliminate undesirable consequences of heating the specimen during the experiments, the emission spectra of Ti in hydrides of various chemical composition were analyzed with the use of the fluorescence method. All the tests were performed on a high-intensity vacuum tube-spectrograph with Johann focusing. The titanium hydrides were prepared and analyzed by V. M. Mikheyeva, and the vanadium hydrides by T. V. Dubovik and G. V. Samsonov. The experiments proved the hypothesis on the "metallization" of the metal-hydrogen bond in the aforementioned compounds and the penetration of 1s-electrons of hydrogen into the vacant 3d-band of the transition metal. This is manifested in the gradual decrease (in comparison with the metal) of intensity of the long wavelength maximum, within the range of the basic edge of the hydride absorption band, and its displacement to the short wavelength side with increasing hydrogen content in the hydrides until this maximum vanishes entirely. A further increase of the hydrogen content in the hydrides does not cause changes in the absorption edge structure of the metal in hydrides. As expected, the long wavelength maximum of absorption in the spectrum of the transition metal in vanadium hydrides vanishes at lesser hydrogen contents in the alloy, than in titanium hydrides. Investigations of the fine structure of the  $K_{\beta}$ -band of titanium

Roentgenospectral analysis of the...

in the hydrides confirm fully the conclusions on the nature of the chemical bond forces in these compounds. The conclusions were drawn from the analysis of experimental data on the absorption spectra of elements in these compounds. However, the peculiarities of the fine structure of Ti emission bands in the hydrides and its changes, depending on the composition of the compounds, may indicate changes in the nature of forces of chemical interaction between hydrogen and metal in the alloys, which differ in the degree of completeness of the transition metal 3d-band. It can also be considered that 1s-electrons of hydrogen do not completely lose their "individual" nature when a generalized sd-band is formed in the hydrides and that the effective hydrogen charge is not equal to 1 and can be different for hydrides rich or poor in hydrogen. This explains also the incomplete vanishing of the  $K_{\beta''}$ -satellite in the emission spectra of titanium in the hydrides. There are 5 figures.

AUTHORS: Zhurauskene, E., Vaychyunas, S.

TITLE: Relationships between the absorption and luminescence spectra of several aromatic compounds

SOURCE: AN Lit SSR. Litovskiy fizicheskiy sbornik. v.1, no.1-2, 1961, 179-186

TOPIC TAGS: absorption spectrum luminescence spectrum, aromatic compound, impurity center, pyrene solution in n-paraffine, 3,4-benzopyrene solution in n-paraffine, n-hexane, n-octane, pyrene solution, n-paraffine, 3,4-benzopyrene solution

ABSTRACT: The paper provides a survey of existing literature on the luminescence and absorption spectra of various monomolecular aromatic hydrocarbons in frozen n-paraffine solutions, and describes the results of an experimental investigation of the effect of the rate of freezing on the absorption spectrum of pyrene in n-heptane. A comparison is provided of the luminescence and absorption spectra of pyrene as against those of 3,4-benzopyrene in n-paraffine solutions at 77K.<sup>1</sup> It is apparent that in some solvents (pyrene in n-hexane and n-octane, 3,4-benzopyrene in n-heptane and n-hexane) several oscillation-band series can be found in the absorption and fluorescence spectra, the number of which is identical in both spectra.

Card 1/2

L 18581-63

ACCESSION NR: AT3002113

The electron transition 0'-0" in these spectra is represented by several resonance lines which correspond to the 0'-0" transitions in various impurity centers. In solution of pyrene in n-heptane and of 3,4-benzopyrene in n-octane, fluorescence and absorption spectra with a differing number of oscillatory bands were found. It is also shown that the number of oscillatory-band series in the absorption spectrum of solutions of 3,4-benzopyrene in n-octane increases because of the unequal time employed in freezing. The appearance of the differences and of a multiplet structure is attributed to the presence of differing impurity centers, the number of which depends on the method of freezing and, also apparently, on the oscillations of the crystalline lattice of the solvent. Orig. art. has 3 figures.

1. Biological activities of the grape on rootstock feeding.  
L. V. Malivanyova and M. S. Shuravek. Pestsafir i Pests  
gradator. 3.5.2. R. 15, No. 4, 35-37 (1971).  
Rootstock feeding (spraying 3 cluster in 10 days with 50% of 1% KCl, 1%  
K<sub>2</sub>SO<sub>4</sub>, 1% NaHCO<sub>3</sub>, or 4% Cu(CNO)<sub>2</sub>) gives impinged  
flavor, and, in the case of KCl, a more uniform and intense  
color, in 10 grape varieties. Good grape flavor was defined  
as pheno-acidometric index (ratio of sugar content in % to  
titratable acidity in g/l) > 6. In 10 rootstock feeding  
with 1.5% NaHCO<sub>3</sub> values of the pheno-acid and titratable  
acidity ratio were observed to be higher and the ratio of  
these clusters was somewhat lower. In which the sucrose  
percentage feeding increased the intensity of flavor pheno-acid  
in the case of the cluster 10 times. This technique caused con-  
siderable increase in grape juice quality and therefore its  
marketing, especially with K and P roots. K and P fed clear  
low red clusters, whereas rootstock 3 cluster caused purple  
feeding, and Cu(CNO)<sub>2</sub> caused yellowish feeding. The whole  
feeding process was more intensive in case of Cu. This process  
was expected to give better crop yields. A. W. Italy

ratus of the stomach was impregnated with silver by the method of Bielschowsky and Gross. The ganglion cells and the nerve fibers proved to be more vulnerable than the sensory nerve endings. The ganglion cells showed an increased uptake of silver, with changes in shape and size. Some cells showed vacuolization or underwent complete disintegration. The nerve fibers also showed an increased uptake of silver, with vacuolization of the axis cylinders and various thickenings, and some fibers even disintegrated completely. Changes in the sensory nerve endings were only slight, consisting of an increased uptake of silver and swelling confined to short stretches of some of the terminal processes. No relation between the described changes and the diet could be established. There are 6 figures.

AUTHOR: Zhuravel', P.A. SOV-21-58-4-25/29

TITLE: On Enriching the Piscine Food Supply of Crimean Reservoirs  
(Ob obogashchenii kormovoy bazy ryb vodokhranilishch Kryma)

PERIODICAL: Dopovidi Akademii nauk Ukrains'koi RSR, 1958, Nr 4,  
pp 456-458 (USSR)

ABSTRACT: All investigators of freshwater reservoirs of the Crimea, such as Ya.Ya. Tseyeb, I.I. Puzanov, G.P. Trifonov, S.N. Ulomskiy, point out an underpopulation of fish and food fauna, which reduces the fish catch in these basins. The underpopulation of the fauna may be explained both by the history of this region, as was suggested by I.I. Puzanov and Ya.Ya. Tseyeb, and by contemporary conditions. The author's investigations show that favorable conditions have developed in the Crimean reservoirs for a number of faunal forms which are absent in the rivers feeding these reservoirs. Work on introducing fish species and food organisms into some Crimean reservoirs, initiated at the author's suggestion, by Crimean organization (aided by the hydrobiological research institutions of Dnepropetrovsk and Kiev) in the spring of 1955, have already yielded the first positive results. Chemical and hydrobiological studies of the reservoirs into which

TITLE: Enrichment of the Fresh Water Fauna of the Crimea (Obogashcheniye fauny presnykh vodoyemov Kryma)

PERIODICAL: Priroda, 1958, Nr 6, p 55-56 (USSR)

ABSTRACT: The ponds and water reservoirs of the Crimea are mainly inhabited by small river fish and a few species of bottom animals. Some of these reservoirs are well suited for raising commercial fish and invertebrate-feeding animals which do not exist in the water-supplying rivers. In 1955, various Crimean organizations, in cooperation with hydrobiological scientific institutions of Dnepropetrovsk and Kiev, began to put new kinds of fish (the pike perch, bream, carp and others) into these ponds and reservoirs. This called for the introduction of feeding animals, and the Dnepropetrovskiy nauchno-issledovatel'skiy institut hidrobiologii Gosuniversiteta (Dnepropetrovsk Scientific Research Institute of Hydro-Biology of the State University) started putting out experimentally such animals as oligochaete worms, branchiate mollusks and crustacea. Professor G.B. Mel'nikov controls the chemical and hydrobiological investigations of the stocked reservoirs and the newly introduced fish and invertebrates.

New Crustacean Species in the Vasil'kov Reservoir on the  
Volchaya River (Novyye vidy rakoobraznykh v Vasil'kovskom  
vodokhranilishche na reke Volch'yey)

PERIODICAL:

Dopovidi Akademii nauk Ukrains'koi RSR, 1958, Nr 8,  
pp 891-892 (USSR)

ABSTRACT:

Gammaridae and Mysidae were introduced into the Vasil'kov reservoir on the Volch'ya river (affluent of the Samara-Dneprovskaya) as an experiment. Of the Mysidae, the species introduced were Mesomysis kowalewskyi Czern. and Limnomysis benedeni Czern. The planted organisms soon became habituated to the environment and spread all over the reservoir and upstream. In view of the fact that Mysidae are active filterers, they should play an important part as biofilter components in potable water reservoirs after more development. There are 6 references, 5 of which are Soviet and 1 Hungarian.

A Mysis That is New for the Dnepr System - Hemimysis  
Anomala Sars - in the Dnepr Reservoir (Novaya dlya  
sistemy Dnepra mizida - Hemimysis anomala Sars v  
Dneprovskom vodokhranilishche)

PERIODICAL:

Dopovidi Akademii nauk Ukrains'koi RSR, 1959, Nr 1,  
pp 85-87 (USSR)

ABSTRACT:

A Hemimysis anomala Sars was revealed in the lower,  
near the dam portion of the Dnepr reservoir (Lenin  
lake) in September 1958 at depths of 5-30 m and more.  
It was brought into the reservoir in 1957, together  
with the estuary fauna caught in the upper portion  
of the Dnepr estuary, and the lower (estuary-like)  
Ingulets river, to stock the new reservoir. The  
mysis now behaves like a deep-water species. The  
dragging of the bottom was performed by the author,

Sars - in the Dnepr Reservoir

and a group of workers of the Dnepropetrovsk Institute of Hydrobiology, which included V.L. Bulakh, P.Ya. Lavrinenko. The Hemimysis anomala was transplanted to breed in the Dnepr estuary and Dnepr reservoir areas, to provide forage for the fish.

On the Study of the Hydrobiology of the Makortovskiy Reservoir in the Krivoy Rog Basin (K izucheniyu gidrobiologii Makortovskogo vodokhranilishcha v Krivorozhskom basseyne)

PERIODICAL:

Dopovidia Akademii nauk Ukrains'koi RSR, 1959, Nr 3,  
pp 309-311 (USSR)

ABSTRACT:

In order to secure access to certain iron ore deposits of the Krivoy Rog Basin, a section of the Saksagan' river was diverted creating several water reservoirs, the largest of which is the Makortovskiy reservoir, located within the Pyatikhatskiy and Sofiyevskiy rayons of the Dnepropetrovskaya oblast'. Its area of lower banked-up water is 2,000 hectares. The depth at the dam is about 20 m. It was filled in 1957. A considerable variety of mollusks, higher crustaceans, fish, etc, has already been introduced into the reservoir, and more will follow. This undertaking and the study
